A hardware button press is the most common reason a reset will occur. A hardware event is typically defined as a single event that cannot be recovered from, such as a bad connection or switch failure. A software event can be recovered from (e.g. a system crash), but is rare compared to a hardware event. A software event can also be caused by the operating system. For example, a memory leak in the operating system could cause a crash. A software event can be caused by the use of a debugger or other software to debug the operating system. For example, a software developer may use a debugger to debug a software program (e.g. a kernel). ...tests, it will write the list of tests to an ASCII file. So in the sigma.txt file I will have all the tests: sigma.txt will look like: Test Name - These are some sample tests: Some text here to show the tests in between the quotes. Another set of quotes for the tests. End of tests. OK Looks good. Please run the file ...you would only like this for the infrequent cases of an OS kernel crash. This system crash shows: The Windows event log shows a "Buffer overflow in a heap allocation function" with a hex dump of the crash. The crash dump file is in the "c:\program files\Microsoft\MSA\1064" directory. ...otherwise, this is something a computer repair technician should be able to fix. Please make sure you include enough information to diagnose the problem. Please keep the above question generic enough that it can be used for future support cases. Problem A customer has a failing SSD drive in their RAID1 configuration, and their data is scattered around the system. The client has set up replication using "Rsync between two drives" to keep this data. It can be figured out how to recover the data and move it into a separate NAS for off-line backup. The customer wants to know how to avoid this from happening again and have the customer decide what backup steps should be taken in the future. Solution We wrote a script that collects the info to
